ORIGINAL PAPER

Maximal lineability of the class of Darboux not connectivity maps on $\ensuremath{\mathbb{R}}$

Krzysztof Chris Ciesielski¹

Abstract

We provide an elegant argument showing, in ZFC, that the class PES \ Conn of all functions from \mathbb{R} to \mathbb{R} that are perfectly everywhere surjective (so Darboux) but not connectivity is 2^c-lineable, that is, that there exists a linear subspace of $\mathbb{R}^{\mathbb{R}}$ of dimension 2^c that is contained in (PES \ Conn) \cup {0}. This solves a problem from a 2020 paper of Albkwre, Ciesielski, and Wojciechowski. The construction utilizes a transcendental basis of \mathbb{R} .

1 Introduction and preliminaries

Over the last two decades a lot of mathematicians have been interested in finding the largest possible vector spaces that are contained in various families of real functions, see e.g. survey [4], monograph [3], and the literature cited there. (More recent work in this direction include [2,5,8].) Specifically, given a cardinal number κ , a subset M of a vector space X is said to be κ -*lineable (in X)* provided there exists a linear space $Y \subset M \cup \{0\}$ of dimension κ . This notion was first studied by Vladimir Gurariy [9], even though he did not use the term lineability. He showed that the set of continuous nowhere differentiable functions on [0,1], together with the constant 0 function, contains an infinite-dimensional vector space, that is, it is ω -lineable. In what follows c denotes the cardinality of \mathbb{R} .

The goal of this note is to show that the class PES \ Conn is 2^{c} -lineable, where Conn stands for the class of all *connectivity functions* in $\mathbb{R}^{\mathbb{R}}$ (i.e., from \mathbb{R} to \mathbb{R}), that is, having connected graphs (as subspaces of \mathbb{R}^{2}), while PES is the family of all *perfectly everywhere surjective* maps $f : \mathbb{R} \to \mathbb{R}$, that is, such that $f[P] = \mathbb{R}$ for every non-empty perfect set $P \subset \mathbb{R}$. Notice that every $f \in$ PES is also Darboux (meaning that it has the intermediate value property). The c⁺-lineability of PES \ Conn, under the assumption that c is a regular cardinal number, has been proved in a 2020 paper [1] by G.M. Albkwre, K.C. Ciesielski, and J. Wojciechowski. In that paper the authors also asked [1, problem 4.1(iii)] if 2^c-lineability

Krzysztof Chris Ciesielski KCies@math.wvu.edu

¹ Department of Mathematics, West Virginia University, Morgantown, WV 26506-6310, USA

of PES \ Conn can be proved in ZFC. Below we give an affirmative answer to this question. In fact, Theorem 2.1 answers affirmatively all questions stated in [1, problems 4.1 and 4.2]. For an $f \in \mathbb{R}^{\mathbb{R}}$ its *support* is defined as

$$\operatorname{supp}(f) := \{ x \in \mathbb{R} \colon f(x) \neq 0 \}.$$

Note that we do not take the closure of the set above.

For a family $\mathcal{F} \subseteq \mathbb{R}^{\mathbb{R}}$ of non-zero functions with pairwise disjoint supports let $V_{\mathcal{F}}$ be the collections of all maps $f_s := \sum_{f \in \mathcal{F}} s(f) \cdot f$, where $s : \mathcal{F} \to \{0, 1\}$. Notice that each f_s is well defined and that $V_{\mathcal{F}}$ has cardinality 2^{κ} , where $\kappa = |\mathcal{F}|$ is the cardinality of \mathcal{F} . Let $W_{\mathcal{F}}$ be the linear subspace of $\mathbb{R}^{\mathbb{R}}$ over \mathbb{R} spanned by $V_{\mathcal{F}}$. So, the following remark is obvious.

Remark 1.1 If $|\mathcal{F}| = \mathfrak{c}$, then $W_{\mathcal{F}}$ has dimension $2^{\mathfrak{c}}$.

Recall (see e.g. [6]) that $B \subset \mathbb{R}$ is a *Bernstein set* provided $P \cap B \neq \emptyset \neq P \setminus B$ for every non-empty perfect set $P \subset \mathbb{R}$.

For an $S \subset \mathbb{R}$ let $\mathbb{Q}(S)$ denote the subfield of \mathbb{R} generated by S (i.e., the smallest subfield of \mathbb{R} containing S) and let $\overline{\mathbb{Q}}(S)$ be the algebraic closure of $\mathbb{Q}(S)$ in \mathbb{R} . Recall that S is *algebraically independent* provided $s \notin \overline{\mathbb{Q}}(S \setminus \{s\})$ for every $s \in S$; and that S is a *transcendental basis* provided it is a maximal algebraically independent subset of \mathbb{R} . It is well known that there exists a transcendental basis T that is also a Bernstein set—it can be constructed by an easy transfinite induction.¹ (Compare [6, theorem 7.3.4], where an analogous construction of a Hamel basis that is a Bernstain set is described.)

2 The construction

Let id be the identity map from \mathbb{R} to \mathbb{R} and for $\mathcal{F} \subset \mathbb{R}^{\mathbb{R}}$ let id $\mathcal{F} := \{ \text{id} \cdot f : f \in \mathcal{F} \}.$

Theorem 2.1 There exists a family $\mathcal{F} \subset \mathbb{R}^{\mathbb{R}}$ of cardinality \mathfrak{c} with pairwise disjoint supports such that $W_{id} \cdot \mathcal{F} \subset (\text{PES} \setminus \text{Conn}) \cup \{0\}$. In particular, the class PES $\setminus \text{Conn}$ is $2^{\mathfrak{c}}$ -lineable.

Proof Let $\{b_{\xi} : \xi < \mathfrak{c}\}$ be an enumeration of a transcendental basis *T* that is also a Bernstein set and let $\{B_r^{\eta} : r \in \mathbb{R}, \eta < \mathfrak{c}\}$ be a partition of *T* into Bernstein sets such that for every $r \in \mathbb{R}$ and $\eta < \mathfrak{c}$:

(a) $r \in \overline{\mathbb{Q}}(\{b_{\zeta} : \zeta < \xi\})$ for every $\xi < \mathfrak{c}$ with $b_{\xi} \in B_r^{\eta}$.

Such a partition without the property (a) can be found by an easy transfinite induction. Then, the property (a) can be additionally imposed by removing from each initially constructed set B_r^{η} , with $\eta < \mathfrak{c}$ and $r \neq 0$, a set of cardinality less than \mathfrak{c} and adding each such removed part to B_0^{η} .

For every $r \in \mathbb{R} \setminus \{0\}$ and $\eta < \mathfrak{c}$ put

$$D_r^\eta := r \cdot B_r^\eta,$$

and notice that

(b) the sets in $\{D_r^{\eta} : r \in \mathbb{R} \setminus \{0\} \& \eta < \mathfrak{c}\}$ are Bernstein and pairwise disjoint.

¹ Let $\{P_{\xi}: \xi < \mathfrak{c}\}$ be an enumeration of all non-empty perfect subsets of \mathbb{R} , for every ordinal $\xi < \mathfrak{c}$ choose $b_{\xi} \in P_{\xi} \setminus \overline{\mathbb{Q}}(\{b_{\zeta}: \zeta < \xi\})$. Then $\{b_{\xi}: \xi < \mathfrak{c}\}$ is algebraically independent, so there is a transcendental basis *T* extending it, see e.g. [10]. It is Bernstein, as it and its complement (containing a shift of *T* by 1) intersect every non-empty perfect set.

To see pairwise disjointness, choose distinct $\langle r, \eta \rangle$, $\langle r', \eta' \rangle \in (\mathbb{R} \setminus \{0\}) \times \mathfrak{c}$ and numbers $r \cdot b \in D_r^{\eta}$ and $r' \cdot b' \in D_{r'}^{\eta'}$. We need to show that $r \cdot b \neq r' \cdot b'$. Indeed, $b \neq b'$ as they belong to disjoint sets B_r^{η} and $B_{r'}^{\eta'}$, respectively. So, there are distinct $\xi, \xi' < \mathfrak{c}$ such that $b = b_{\xi}$ and $b' = b_{\xi'}$. We can assume that $\xi' > \xi$. Now, if $r \cdot b = r' \cdot b'$ then, by (a), $b_{\xi'} = b' = (r')^{-1}r \cdot b_{\xi} \in \overline{\mathbb{Q}}(\{b_{\xi} : \zeta < \xi'\})$, contradicting algebraic independence of T. To finish the proof of (b) it is enough to notice that $D_r^{\eta} = r \cdot B_r^{\eta}$ intersects every non-empty perfect set P, as $r^{-1}P$ is perfect and $B_r^{\eta} \cap (r^{-1}P) \neq \emptyset$.

For every $r \in \mathbb{R} \setminus \{0\}$ and $\eta < \mathfrak{c}$ define

$$f_r^{\eta}(x) := \begin{cases} r/x & \text{if } x \in D_r^{\eta} \\ 0 & \text{if } x \in \mathbb{R} \setminus D_r^{\eta} \end{cases}$$

and put

$$f_{\eta} := \sum_{r \in \mathbb{R} \setminus \{0\}} f_r^{\eta}.$$

The functions f_r^{η} and f_{η} are well defined since $0 \notin D_r^{\eta}$ and, by (b), the supports of the maps f_r^{η} are pairwise disjoint. We claim that the family $\mathcal{F} := \{f_{\eta} : \eta < \mathfrak{c}\}$ is as needed.

Indeed, clearly id $\cdot \mathcal{F} = \{ \text{id} \cdot f : f \in \mathcal{F} \}$ consists of c-many distinct functions with pairwise disjoint supports. So, by Remark 1.1, $W_{\text{id} \cdot \mathcal{F}}$ has needed dimension 2^c.

It remains to show that every non-zero $f \in W_{id,\mathcal{F}}$ is in PES \ Conn. To see this, notice that there exist $n \in \{1, 2, 3, \ldots\}, a_1, \ldots, a_n \in \mathbb{R}$, and $f_{s_1}, \ldots, f_{s_n} \in V_{id,\mathcal{F}}$ such that

$$f = \sum_{i=1}^{n} a_i f_{s_i} = \sum_{\eta < \mathfrak{c}} \left(\sum_{i=1}^{n} a_i s_i(\eta) \right) \cdot (\operatorname{id} \cdot f_{\eta}), \tag{1}$$

where $f_{s_i} := \sum_{\eta < c} s_i(\eta) \cdot id \cdot f_\eta$ for appropriate $s_i : c \to \{0, 1\}$. Also, for every $r \in \mathbb{R} \setminus \{0\}$ and $\eta < c$ we have $id \cdot f_r^{\eta} = r \chi_{D_r^{\eta}}$, where χ_D is the characteristic function of D, as $(id \cdot f_\eta)(x) = xf_r^{\eta}(x) = r$ for every $x \in D_r^{\eta}$. In particular,

$$\operatorname{id} \cdot f_{\eta} = \sum_{r \in \mathbb{R} \setminus \{0\}} \operatorname{id} \cdot f_{r}^{\eta} = \sum_{r \in \mathbb{R} \setminus \{0\}} r \chi_{D_{r}^{\eta}}.$$
(2)

Also, there is an $\eta < \mathfrak{c}$ so that the number $c_{\eta} := \sum_{i=1}^{n} a_{i}s_{i}(\eta)$ is non-zero, since f is non-zero. Moreover, since sets $D_{\eta} := \bigcup_{r \in \mathbb{R} \setminus \{0\}} D_{r}^{\eta}$ and $B^{0} := \bigcup_{\eta < \mathfrak{c}} B_{0}^{\eta}$ are Bernstein and disjoint, (1) and (2) imply that for every non-empty perfect $P \subset \mathbb{R}$ we have

$$\mathbb{R} = c_{\eta} \cdot \mathbb{R} = c_{\eta} \cdot \left((\mathrm{id} \cdot f_{\eta}) \upharpoonright (D_{\eta} \cup B^{0}) \right) [P] = \left(f \upharpoonright (D_{\eta} \cup B^{0}) [P] \subset f[P] \right),$$

proving that $f \in PES$.

To finish the proof, it is enough to show that $f \notin \text{Conn.}$ To see this, notice that every c_{η} belongs to the finite set $C := \left\{ \sum_{i=1}^{n} a_i t(i) : t \in \{0, 1\}^{\{1, \dots, n\}} \right\}$. Since B^0 is infinite, we can choose an $a \in B^0$ such that $a \notin \overline{\mathbb{Q}}(C \cup (\mathbb{R} \setminus B^0))$. We claim that

$$f(x) \neq ax \text{ for every } x \in \mathbb{R} \setminus \{0\}.$$
 (3)

Indeed, $f(x) = ax \neq 0$ implies that x = rb for some $\eta < c, r \neq 0$, and $b \in B_r^{\eta}$. But, by (1) and (2), this means that $arb = ax = f(x) = c_{\eta}(\operatorname{id} \cdot f_r^{\eta})(x) = c_{\eta} \cdot r$ and so $a = \frac{c_{\eta}}{b} \in \overline{\mathbb{Q}}(C \cup (\mathbb{R} \setminus B^0))$, contradicting the choice of a.

Deringer

Finally, since $f \in \text{PES}$, its graph is dense, so there exist q > p > 0 such that f(p) > ap and f(q) < aq. But this, together with (3) implies that the three-segment set $(\{p\} \times (-\infty, ap]) \cup \{(x, ax) \colon x \in [p, q]\} \cup (\{q\} \times [aq, \infty))$ separates the graph of f.

As mentioned above, the class D of all Darboux functions obviously contains PES. In particular, Theorem 2.1 immediately implies that

Corollary 2.2 *The class* $D \setminus \text{Conn}$ *is* $2^{\mathfrak{c}}$ *-lineable.*

The results presented in this paper constitute a starting point of an extensive study of the maximal lineabilities for all classes in the algebra of Darboux-like maps on \mathbb{R} . This study is expected to lead to several other papers and a Ph.D. dissertation of Mr. Gbrel Albkwre. For the study of the additivity coefficients for the same classes of functions see [7].
